## DETAILED ACTION

### ***Claim Rejections - 35 USC § 103***

1. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

2. Claims 1-20 are rejected under 35 U.S.C. 103(a) as being unpatentable over Okada et al. US # 5,734,241.

With respect to above claims, Okada et al. disclose a brake control system of a brushless motor that is controlled by an electronic circuit constituted in a semiconductor chip. Wherein Fig. 15 shows rotational control circuit adapted for a spindle motor. In column 12, lines 45-67 Okada et al. teach that during the brake operation the reverse-rotation torque is generated in the rotor by the first brake current of first current level, to thereby perform the brake operation at a full torque. It is interpreted that time required for application of full torque constitutes a first period.

Decreasing the reversing torque is conducted when the rotating speed reaches the absolute number of revolutions (the reference speed), the multi-vibrator 307 generates a low level signal. In response to the low level signal the current control circuit 308 switches from the first brake current to the second level current which is smaller than the first level current. As a result, the braking is performed by a smaller

reverse-rotation torque. The second brake current is gradually decreased, thereby smoothly stopping the rotation. This operation is performed during second time period. The second brake current is gradually decreased, therefore the brake torque will be zero when the motor is almost stopped.

With respect to claims 6, 7, 13 and 14, Fig. 11a-e and 12 show the linear change of the applied signal and stable brake operation.

Hence, it has been obvious to one of ordinary skills in the art, at the time invention was made to use above teaching for smooth control of spindle motor during braking operation to avoid over-braking or underbracing.

The reason is eliminate rotational fluctuation.
